

PRODUCT OVERVIEW

DSS—Identity Management

The Data Synchronization System (DSS) is the core of a new best-of-breed data integration solution. DSS has been designed to move, transform, and validate data between separate systems within the IT infrastructure of an organization. The intrasystem connections that DSS provides can be leveraged to provide Identity Management (IDM) functionality, Enterprise Application Integration (EAI), Configuration Management, as well as Extract, Transform, and Load capabilities. These functions allow organizations

FAST FACTS

What you need to know about DSS

- ⇒ One tool for IDM, EAI and ETL
- ⇒ Implement in weeks instead of months
- ⇒ Connect via API, JDBC, CLI, TEXT, LDAP
- ⇒ Extremely scalable
- ⇒ Full integration with ARMS
- ⇒ Cross-platform browser based access

to reduce process duplication by automatically sharing common data between disparate resources, eliminating the need for manual data updates and duplication. Identity Automation has developed a series of adapters for DSS that provide connections to the most common business applications, thus reducing implementation time by allowing system architects to concentrate efforts on the few systems that require custom connections.

Identity Management is the on going process of creating users within an organization's IT infrastructure, provisioning those users into systems needed to perform their duties, maintaining the user to keep information and access current, and deprovisioning the user when the access is no longer required. A custom IDM solution automates a majority of the processes required to keep an organization's user infrastructure consistent across all connected systems. Furthermore, an IDM solution can be implemented to give users simplified sign-on access to a variety of network accessible resources. These can include email, customer management systems, point of sale terminals, web hosted applications, and just about any other network accessible system, this allows users in the environment to access all of their resources with the same

credential request. If DSS is deployed with the Access Request Management System (ARMS) Account Module, users can self-service their accounts to manage certain attributes such as nicknames and fax numbers, as well as reset passwords, further reducing technology staff workload while improving user satisfaction.

While the improvements to the end-user experience represent a huge potential for increased efficiency, the true power of a DSS brokered IDM solution takes place behind the scenes. Automatic provisioning of users allows for a true Zero-Day start for new employees, once entered into the HRM system DSS will create and populate that user into systems and grant access based on their role. This takes place as soon as approval for the user is given, avoiding the old, protracted process of provisioning a user one system at a time. Deprovisioning of accounts is also automated, ensuring that access is restricted to active users (Zero day stop). DSS can provide additional security enhancements when ARMS is implemented alongside it. Password policy can now be set from a single point to the level required by security policy, rather than rely on users to maintain the correct level. DSS can be configured to operate by event, on a set schedule, or a combination of both. This allows for precise control of all data collected by the organization, ensuring both maximum user up time and complete control of the data in the environment. Finally, DSS can be deployed as a fully managed service giving organizations additional staffing flexibility .

DSS is the next generation of IDM solutions, combining a full featured solution with an intuitive and logical interface. Its array of fully developed integration adapters allows DSS to be implemented using RAPiD iDENTiTY deployment methodology in a fraction of the time required by other products. Delivering the cost and workload reductions months ahead of other products, while still providing an effective, fully functional solution.
